1

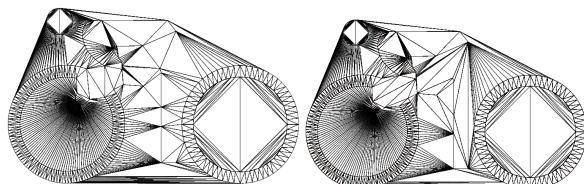

Triangulation of 2D points

- What if the Delaunay triangulation does not comply the boundaries of the domain or a network of constraints?
- Constraint : a segment to be inserted into the triangulation

2

Case of a digital 2D or 2D½ model

- Unconstrained Triangulation
- Constrained Triangulation

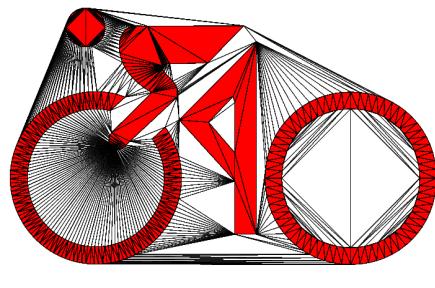

Images by B. Kornberger

3

Case of a digital 2D or 2D½ model

- Constrained triangulation

4

Constrained triangulation of 2D points

- What if the Delaunay triangulation does not comply the boundaries of the domain or a network of constraints?
- We insert the constraints into the triangulation
 - Using the *flip* operation
 - Flip of edges intersecting the constraint edges
 - Orient the constraint edges to set an order for the flip of the intersecting edges

5

Constrained triangulation of 2D points

- What about the non constrained edges?
 - Slightly modify the (locally)-Delaunay Criterion
 - A constraint is seen as a wall stopping the visibility
 - A vertex can be located inside a circumscribed circle if it is not visible from inside the triangle
 - Flip any un-constrained edge that is non locally Delaunay

6

5

6

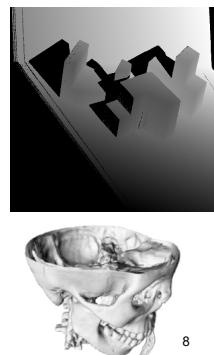

Incremental Constrained triangulation of 2D points

- Incremental insertion of a point in a constrained 2D triangulation
 - Constrained edges cannot be flipped
 - Slightly modify the (locally)-Delaunay Criterion
 - A constraint is seen as a wall stopping the visibility
 - A vertex can be located inside a circumscribed circle if it is not visible from inside the triangle

7

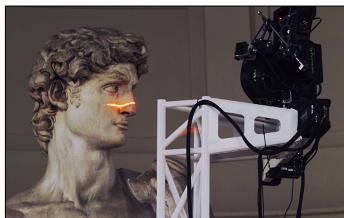

3D Shape Modelling

- How to obtain a mesh?
- Input data
 - Range images
 - Volumetric voxel images
 - CAD/CAM
 - Dirty meshes provided by graphic designers
 - 2D Images + stereovision

8

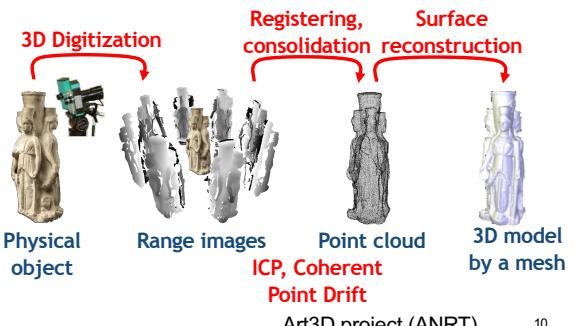

3D objects digitization

Laser scanner (Michelangelo Project)

9

From 3D digitization to surface reconstruction

10

Shape Reconstruction

- Problem of 2D reconstruction
 - Reconstruct a curve from 2D input point samples on that curve
- Problem of 3D reconstruction
 - Reconstruct a surface from 3D input point samples on that surface

11

Case of a digital terrain model

- Data can be parameterized as a height function with respect to a reference plane (2D ½ dimension)
- Delaunay triangulation of the points projected on the reference plane
 - Triangulation maximizing the angles of the triangle projected on the 2D plane, not the angles of the 3D triangles

12

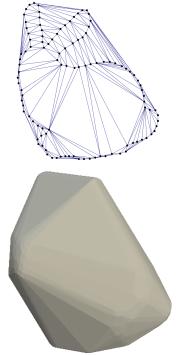

Case of a digital terrain model

- How to better consider the height information?
 - Find the triangulation maximizing the angles of the 3D triangles
 - Remark : each pair of adjacent triangles can locally be flattened with a preservation of the angles
 - It is possible to reuse Lawson's flipping algorithm, without guaranteeing a global optimum
 - Non Delaunay edges $\Pi - (\alpha + \beta) < 0$

13

Mesh generation from 2D or 3D point set

- 2D Reconstruction
 - Look for the curve as a sub-graph of the 2D Delaunay triangulation
 - Provided it should be present in it!
- 3D Reconstruction
 - Look for the surface mesh as a sub-graph of the 3D Delaunay triangulation

14

In the following...

- We will distinguish
 - The original shape on which the input points have been sampled and which one seeks to approximate
 - The provided samples
- Care should be taken to maintain an equivalence between **continuous** and **discrete** notions

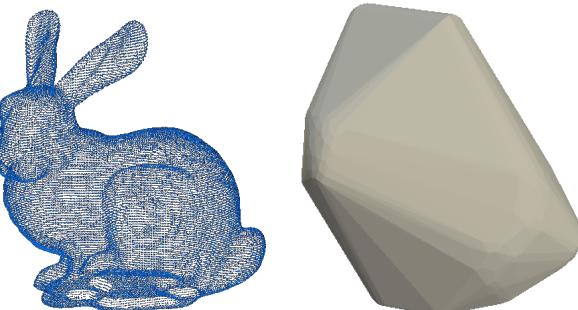

15

One of the first reconstruction algorithm

- CRUST (Amenta et al)
 - Algorithm provided with necessary and sufficient conditions on the **sampling density** to guarantee the result of the reconstruction
 - Minimal Sampling density characterized by using the « Local Feature Size » : distance from the **surface points** to the **skeleton** (medial axis) of the shape
 - Skeleton : **set of maximal balls centers** approximated by **Voronoi Centers**

16

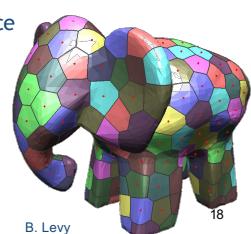

Other algorithms based on Delaunay

17

Restricted Voronoi Diagram

- Given a set of points on a surface
 - Restricted Voronoi cell :
 - Intersection between a Voronoi cell and the surface
 - Can be used to construct triangles between points with adjacent restricted Voronoi cells

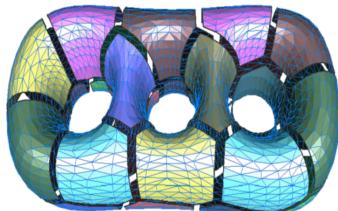

B. Levy

18

Voronoi diagram restricted to a surface

- Restricted Voronoi diagram

- Intersections between the 3D Voronoi cells and the surface of the original shape (**if ever we have it!!**)

B. Levy

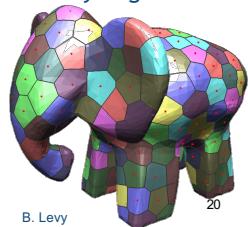

19

19

Restricted Delaunay Triangulation

- Restricted Delaunay :

- Defined by duality
- Each adjacency between 2 restricted Voronoi cells results in a restricted Delaunay edge
- Creation of triangles of restricted Delaunay by duality to a vertex of Restricted Voronoi

B. Levy

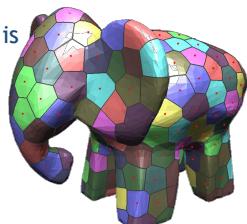

20

20

Restricted Delaunay Triangulation

- Edelsbrunner and Shah's theorem[1997]

- If each face of the Restricted Voronoi diagram is homeomorphic to a topological disc, then the restricted Delaunay triangulation is homeomorphic to the unknown surface.

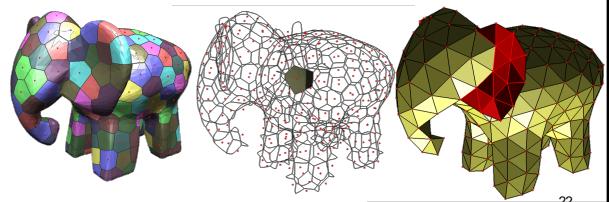

B. Levy

21

21

Restricted Delaunay Triangulation

- Topological disk property not satisfied for insufficient sampling....

B. Levy

22

22

Restricted Delaunay Triangulation

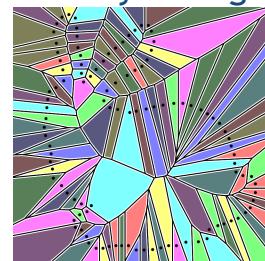

- In presence of an ε -sampling with $\varepsilon < 0.1$, the property of the topological disk is satisfied [Amenta and Bern 99]
- The problem is that we do not know the original surface, and we need it to build the restricted Voronoi cells and the associated dual triangulation...

23

23

What if the surface is unknown?

Cocone : An other reconstruction approach using Voronoi diagram and Delaunay triangulation

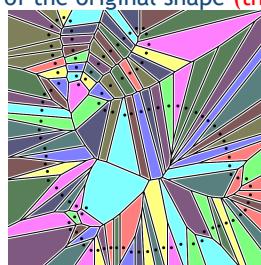

24

24

Voronoi diagram restricted to a curve

- Restricted Voronoi diagram

- Intersections between the 2D Voronoi cells and the curve of the original shape (**that we do not know !!**)

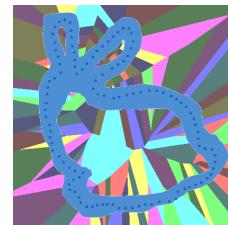

B. Levy

25

Cocone

- Idea: find some kind of thickened version of the original surface and make a restricted Delaunay triangulation of this thickened version

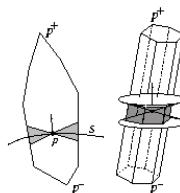

B. Levy

26

Cocone

- Thickening of the unknown surface :

- For this purpose, a Cocone is placed at each sampled point [Amenta et al 2000]
- Positioning using the tangent plane
 - using unoriented normal or estimating it from Voronoi 3D cell
- A triangle is created from every triplet of adjacent cocones
- Residual filtering still needed (non manifoldness) ²⁷

27

Other reconstruction approaches based on an approximation of the skeleton

28

Power Crust

- Observation :

- any point of a compact surface is on the boundary of two maximal balls centered on the skeleton
- an outer ball and an inner medial ball

- Use the idea that the inside of any closed surface is a union of balls

29

Back to the medial axis/ skeleton

- In 2D :

- Center of the maximal balls contained within the curve
- All points that have more than one nearest neighbor on the curve

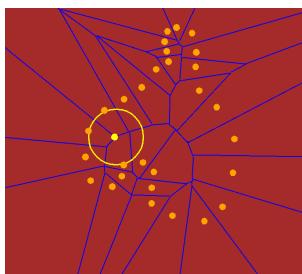

30

Back to the medial axis

- 2D approximation :

- Voronoi balls are the discrete equivalent of maximal balls

31

31

2D reconstruction

- By approximating the medial axis

- We can therefore approximate a 2D shape as a union of inner Voronoi balls
- What we need to know is which balls are inside (resp. outside) or at least which ones have different signs

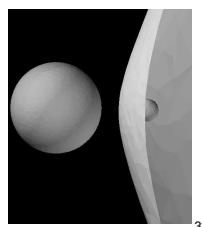

32

32

Back to the Medial Axis

- In 3D:

- The medial axis of a surface is a surface (possibly with pieces of curves)

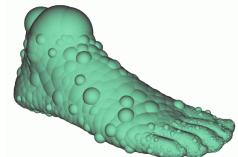

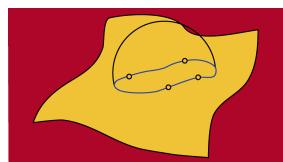

33

33

3D reconstruction by approximating the Medial Axis

- 3D approximation:

- Beware of Voronoi balls that are centered on the surface (sliver)
- Even for a good surface sampling

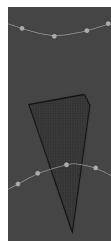

34

Back to Voronoi

- In case of a dense and noise free sampling

- Long and thin Voronoi cells,
- Direction aligned with the normal to the surface
- With extremities close to the medial axis

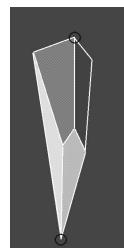

35

35

Poles

- Poles

- Voronoi vertices at the extremities of the elongated cells

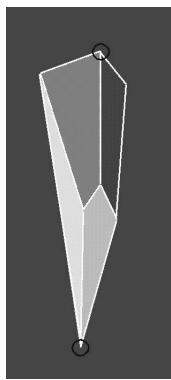

36

36

Poles

- Approximation

- Let V_p be the Voronoi cell of a point p
- Positive pole p^+ : Voronoï vertex of V_p furthest from p .
- Vector pole pp^+ : approximation of the normal direction at p .
- The negative pole p^- : vertex of V_p furthest from p^+ in the direction opposite to the vector pp^+

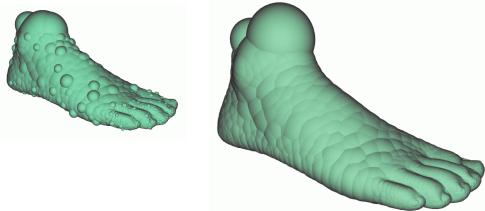

37

3D reconstruction by approximating the medial axis

- 3D approximation:

- Retain only polar balls (centered on the poles)

Amenta and Bern 98

38

3D reconstruction by approximating the medial axis

- 3D approximation:

- Retain only polar balls (centered on the poles)
- Yes, but which ones?

39

Power Crust

- It is difficult to know which polar balls are internal
- However, local criteria make it possible to distinguish polar balls of different natures
 - Two adjacent "deeply intersecting" polar balls are considered to be on the same side of the surface
 - Two "barely intersecting" polar balls are one internal and the other external

40

39

40

Power Crust

- Labelling of polar balls

- Global heuristics

- "External" labelling of the poles incident to a large enclosing box
- Propagation of labels:

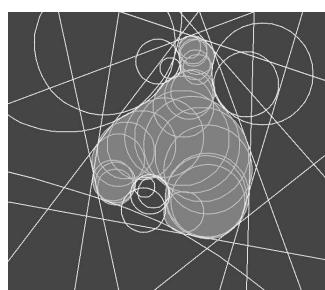

- For any pole p labelled "external".
 - each unlabelled neighbor q such that the polar balls associated with p and q intersect deeply is labelled "external".
- For each point s of S considering p is the pole, the other pole is labelled internal.

- For any pole labelled "internal".
 - Symmetrical work
- Using a priority queue

41

Power Crust

- How to switch from a set of balls to a mesh?

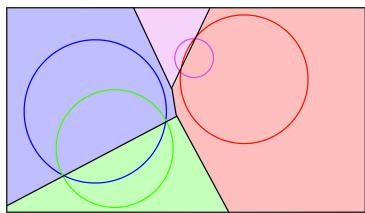

42

41

42

Power Crust

- How to switch from a set of balls to a mesh?
 - Construction of a ball **power diagram**.

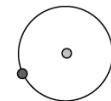

43

43

Power diagram

- Can be seen as a Voronoï diagram of balls with an adhoc metric
 - Ball B of center c and radius r
 - Power distance of a point x with respect to B :

$$d_{\text{pow}} = d^2(c, x) - r^2$$

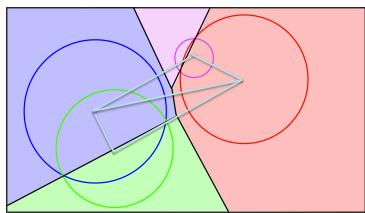

44

44

Power Crust

- Note: The dual of a power diagram is a triangulation connecting the centers of the circles (Regular triangulation)

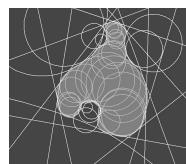

45

45

Power Crust

- Construction of a power diagram using polar balls
- Reconstructed surface:
 - set of facets of the diagram whose dual edges link an inner pole and an outer pole.

46

46

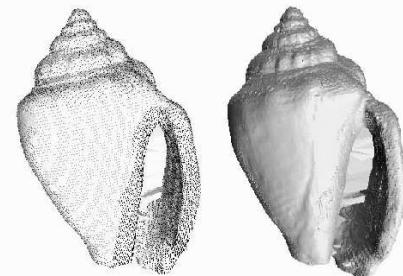

Power-Crust Results

47

47

Power Crust results

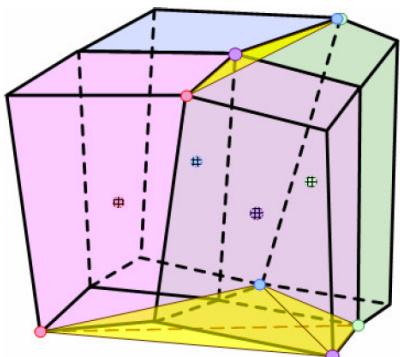

- Natural filling of the holes

48

48

Power-Crust Result

49

Power Crust

- Robustness:

- The output mesh is the boundary of a solid (by construction) but does not only contain triangles
- No surface extraction or hole filling steps

- Correctness:

- Theoretical results that relate the geometric and topological validity of the result to the quality of the sampling

50

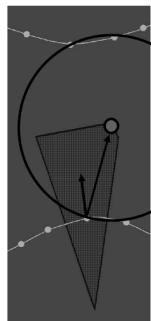

49

50

Power Crust

- Correctness:

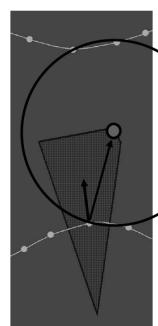

- All the (wide) polar balls passing through a sample s are nearly tangent to the surface in s

51

Power Crust

- Given a ϵ -sampling of a surface S , the angle between the normal at S in s and the vector joining s to one of its poles is in $O(\epsilon)$

52

51

52

Power Crust Results

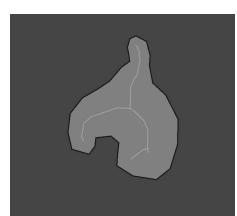

- Robustness to noise

53

Power Crust

- Power crust also provides an approximation of the medial axis
- Connection of the inner poles with adjacent cells in the power diagram

54

53

54

Power Crust results

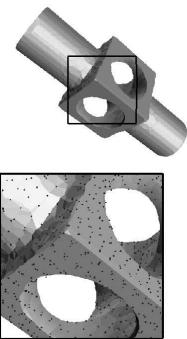

- Simplification of the skeleton (noisy samples or not)

55

Power Crust Results

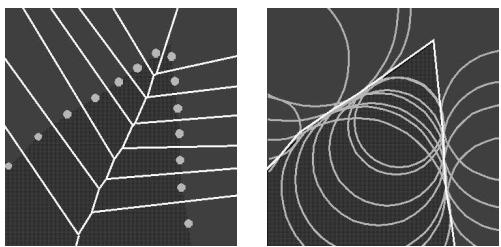

- Sharp edges can be inferred

56

Power Crust results

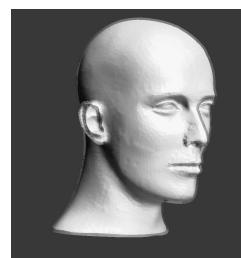

- Respect of sharp edges :
 - Ignore poles associated with malformed Voronoi cells

57

Offset surface management

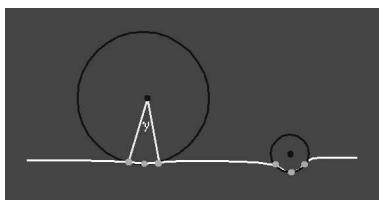

- Narrowing of the internal polar balls
- Widening of the external polar balls

58

Handling noise

- By simplifying the medial axis
- Delete polar balls associated with vertices that are too close to the pole

59

59

10
